Q1 Which of the following are ways to show that a language is in NP?

1 Point

(select all that apply)

create a deterministic poly time decider

create a non-deterministic poly time decider

create a deterministic poly time verifier

create a non-deterministic poly time verifier

Last Time: Poly Time Complexity Class (**P**)

P is the class of languages that are decidable in polynomial time on a deterministic single-tape Turing machine. In other words,

$$P = \bigcup_k \text{TIME}(n^k).$$

- Corresponds to “realistically” solvable problems:
 - Problems in **P**
 - = “solvable” or “tractable”
 - Problems outside **P**
 - = “unsolvable” or “intractable”

Last Time: 3 Problems in P

- A Graph Problem:

$$PATH = \{\langle G, s, t \rangle \mid G \text{ is a directed graph that has a directed path from } s \text{ to } t\}$$

“search” problem

- A Number Problem:

$$RELPRIME = \{\langle x, y \rangle \mid x \text{ and } y \text{ are relatively prime}\}$$

- A CFL Problem:

Every context-free language is a member of P

Search vs Verification

- Search problems are often **unsolvable**
- But, verification of a search result is usually **solvable**

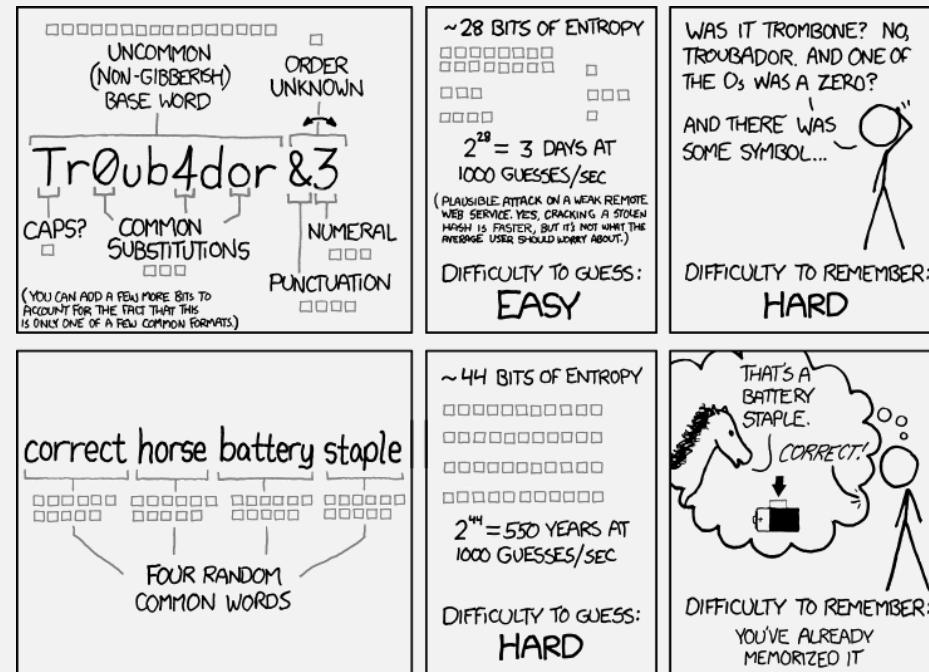

EXAMPLES

• FACTORING

- **Unsolvable:** Find factors of 8633
 - Must “try all” possibilities
- **Solvable:** Verify 89 and 97 are factors of 8633
 - Just do multiplication

• PASSWORDS

- **Unsolvable:** Find my umb.edu password
- **Solvable:** Verify whether my umb.edu password is ...
 - “correct horse battery staple”

THROUGH 20 YEARS OF EFFORT, WE'VE SUCCESSFULLY TRAINED EVERYONE TO USE PASSWORDS THAT ARE HARD FOR HUMANS TO REMEMBER, BUT EASY FOR COMPUTERS TO GUESS.

The *PATH* Problem

$PATH = \{\langle G, s, t \rangle \mid G \text{ is a directed graph that has a directed path from } s \text{ to } t\}$

- It's a **search problem**:

- **Exponential time** (brute force) algorithm (n^n):
 - Check all n^n possible paths and see if any connects s and t
- **Polynomial time** algorithm:
 - Do a breadth-first search (roughly), marking “seen” nodes as we go ($n = \# \text{ nodes}$)

PROOF A polynomial time algorithm M for *PATH* operates as follows.

M = “On input $\langle G, s, t \rangle$, where G is a directed graph with nodes s and t :

1. Place a mark on node s .
2. Repeat the following until no additional nodes are marked:
3. Scan all the edges of G . If an edge (a, b) is found going from a marked node a to an unmarked node b , mark node b .
4. If t is marked, *accept*. Otherwise, *reject*.”

$O(n^3)$

Verifying a *PATH*

$PATH = \{\langle G, s, t \rangle \mid G \text{ is a directed graph that has a directed path from } s \text{ to } t\}$

The **verification** problem:

- Given some path p in G , check that it is a path from s to t

- Let m = length of longest possible path = # edges

NOTE: extra argument p ,
“Verifying” an answer requires
having a potential answer to check!

Verifier V = On input $\langle G, s, t, p \rangle$, where p is some set of edges:

- Check some edge in p has “from” node s ; mark and set it as “current” edge
 - Max steps = $O(m)$
- Loop:** While there remains unmarked edges in p :
 - Find the “next” edge in p , whose “from” node is the “to” node of “current” edge
 - If found, then mark that edge and set it as “current” also reject
 - Each loop iteration: $O(m)$
 - # loops: $O(m)$
 - Total looping time = $O(m^2)$
- Check “current” edge has “to” node t ; if yes accept, else reject

- Total time = $O(m) + O(m^2) = O(m^2)$ = polynomial in m

$PATH$ can be verified
in polynomial time

Verifiers, Formally

$PATH = \{\langle G, s, t \rangle \mid G \text{ is a directed graph that has a directed path from } s \text{ to } t\}$

A *verifier* for a language A is an algorithm V , where
$$A = \{w \mid V \text{ accepts } \langle w, c \rangle \text{ for some string } c\}$$

Decider ...

A possible

... with extra argument:
can be any string that helps
to find a result in poly time
(is often just a potential
result itself)

certificate, or *proof*

We measure the time of a verifier only in terms of the length of w ,
so a *polynomial time verifier* runs in polynomial time in the length
of w . A language A is *polynomially verifiable* if it has a polynomial
time verifier.

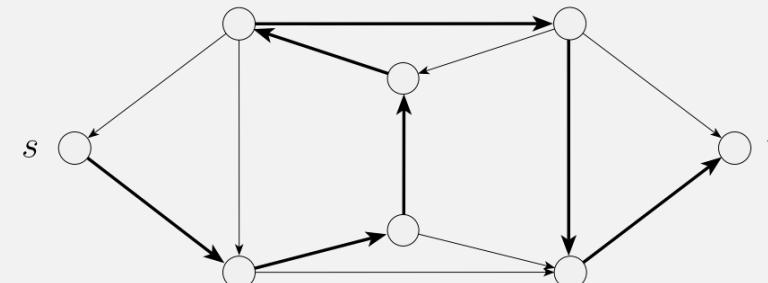

- NOTE: a certificate c must be at most length n^k , where $n = \text{length of } w$
 - Why? Because it takes time n^k to read it

So $PATH$ is polynomially verifiable

The *HAMPATH* Problem

HAMPATH = { $\langle G, s, t \rangle | G$ is a directed graph
with a Hamiltonian path from s to t }

- A **Hamiltonian path** goes through every node in the graph

- The **Search** problem:
 - **Exponential time** (brute force) algorithm:
 - Check all possible paths and see if any connect s and t using all nodes
 - **Polynomial time** algorithm: **???**
 - We don't know if there is one!!!
- The **Verification** problem:
 - Still $O(m^2)$! (same verifier for *PATH*)
 - *HAMPATH* is polynomially verifiable, but not polynomially decidable

The class **NP**

DEFINITION

NP is the class of languages that have polynomial time verifiers.

- *PATH* is in **NP**, and **P**
- *HAMPATH* is in **NP**, but it's unknown whether it's in **P**

NP = Nondeterministic polynomial time

NP is the class of languages that have polynomial time verifiers.

THEOREM

A language is in NP iff it is decided by some nondeterministic polynomial time Turing machine.

⇒ If a language is in NP, then it has a non-deterministic poly time decider

• We know: If a lang L is in NP, then it has a poly time verifier V

• Need to: create NTM deciding L :

On input w =

• Nondeterministically run V with w and all possible poly length certificates c

NOTE: a verifier cert is usually a potential “answer”, but does not have to be (like here)

Certificate c specifies a path

⇐ If a language has a non-deterministic poly time decider, then it is in NP

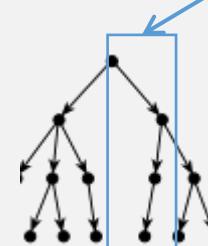

• We know: L has NTM decider N ,

• Need to: show L is in NP, i.e., create polytime verifier V :

On input $\langle w, c \rangle$ = Potentially exponential slowdown?

But which path to take?

- Convert N to deterministic TM, and run it on w , but take only one computation path
- Let certificate c dictate which computation path to follow

Deterministic
(verifier) TMs
cannot “call” non-
deterministic TMs

Converting NTM to
deterministic TM
is exponentially
slower!

NP

$\text{NTIME}(t(n)) = \{L \mid L \text{ is a language decided by an } O(t(n)) \text{ time nondeterministic Turing machine}\}.$

$$\text{NP} = \bigcup_k \text{NTIME}(n^k)$$

NP = Nondeterministic polynomial time

NP vs P

P is the class of languages that are decidable in polynomial time on a deterministic single-tape Turing machine. In other words,

$$P = \bigcup_k \text{TIME}(n^k).$$

P = Deterministic polynomial time

NTIME($t(n)$) = { $L | L$ is a language decided by an $O(t(n))$ time nondeterministic Turing machine}.

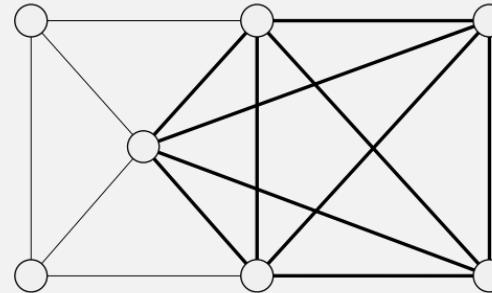

$$NP = \bigcup_k \text{NTIME}(n^k)$$

Also, NP = Deterministic polynomial time verification

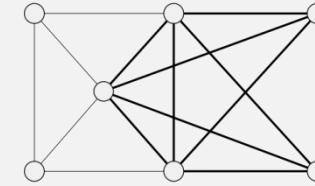

NP = Nondeterministic polynomial time

More NP Problems

- $CLIQUE = \{\langle G, k \rangle \mid G \text{ is an undirected graph with a } k\text{-clique}\}$
 - A clique is a subgraph where every two nodes are connected
 - A k -clique contains k nodes

- $SUBSET-SUM = \{\langle S, t \rangle \mid S = \{x_1, \dots, x_k\}, \text{ and for some } \{y_1, \dots, y_l\} \subseteq \{x_1, \dots, x_k\}, \text{ we have } \sum y_i = t\}$

Theorem: *CLIQUE* is in NP

$CLIQUE = \{\langle G, k \rangle \mid G \text{ is an undirected graph with a } k\text{-clique}\}$

PROOF IDEA The clique is the certificate.

Let $n = \# \text{ nodes in } G$

PROOF The following is a **verifier V** for *CLIQUE*.

c is at most n

$V = \text{"On input } \langle \langle G, k \rangle, c \rangle:$

1. Test whether c is a subgraph with k nodes in G .
2. Test whether G contains all edges connecting nodes in c .
3. If both pass, *accept*; otherwise, *reject*."

For each: node in c ,
check whether it's in G
 $O(n^2)$

For each: pair of nodes in c ,
check whether there's an edge in G :
 $O(n^2)$

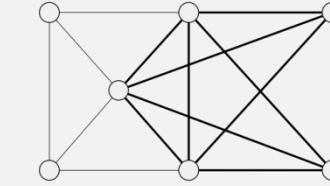

A **verifier** for a language A is an algorithm V , where

$$A = \{w \mid V \text{ accepts } \langle w, c \rangle \text{ for some string } c\}.$$

We measure the time of a verifier only in terms of the length of w , so a **polynomial time verifier** runs in polynomial time in the length of w . A language A is **polynomially verifiable** if it has a polynomial time verifier.

How to prove a language is in **NP**:
Proof technique #1: **create a verifier**

NP is the class of languages that have polynomial time verifiers.

Proof 2: *CLIQUE* is in NP

$CLIQUE = \{\langle G, k \rangle \mid G \text{ is an undirected graph with a } k\text{-clique}\}$

$\boxed{N = \text{"On input } \langle G, k \rangle, \text{ where } G \text{ is a graph:}}$

1. Nondeterministically select a subset c of k nodes of G .
2. Test whether G contains all edges connecting nodes in c .
3. If yes, *accept*; otherwise, *reject*.

“try all subgraphs”

Checking whether a
subgraph is clique:
 $O(n^2)$

To prove a lang L is in NP, create either a:

1. Deterministic poly time verifier
2. Nondeterministic poly time decider

Don't forget to count the steps

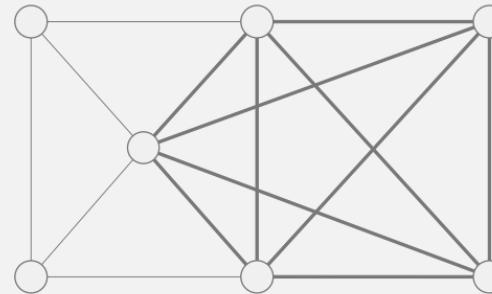

How to prove a language is in NP:
Proof technique #2: create an NTM

THEOREM

A language is in NP iff it is decided by some nondeterministic polynomial time Turing machine.

More NP Problems

- $CLIQUE = \{\langle G, k \rangle \mid G \text{ is an undirected graph with a } k\text{-clique}\}$
 - A clique is a subgraph where every two nodes are connected
 - A k -clique contains k nodes

- $SUBSET-SUM = \{\langle S, t \rangle \mid S = \{x_1, \dots, x_k\}, \text{ and for some } \{y_1, \dots, y_l\} \subseteq \{x_1, \dots, x_k\}, \text{ we have } \sum y_i = t\}$
 - Some subset of a set of numbers S must sum to some total t
 - e.g., $\langle \{4, 11, 16, 21, 27\}, 25 \rangle \in SUBSET-SUM$

Theorem: *SUBSET-SUM* is in NP

SUBSET-SUM = { $\langle S, t \rangle$ | $S = \{x_1, \dots, x_k\}$, and for some $\{y_1, \dots, y_l\} \subseteq \{x_1, \dots, x_k\}$, we have $\sum y_i = t$ }

PROOF IDEA The subset is the certificate.

To prove a lang is in NP, create either:

1. Deterministic poly time verifier
2. Nondeterministic poly time decider

PROOF The following is a **verifier** V for *SUBSET-SUM*.

V = “On input $\langle \langle S, t \rangle, c \rangle$:

1. Test whether c is a collection of numbers that sum to t .
2. Test whether S contains all the numbers in c .
3. If both pass, *accept*; otherwise, *reject*.”

Runtime?

Proof 2: *SUBSET-SUM* is in NP

SUBSET-SUM = { $\langle S, t \rangle$ | $S = \{x_1, \dots, x_k\}$, and for some $\{y_1, \dots, y_l\} \subseteq \{x_1, \dots, x_k\}$, we have $\sum y_i = t$ }

To prove a lang is in NP, create either:

1. Deterministic poly time verifier
2. Nondeterministic poly time decider

ALTERNATIVE PROOF We can also prove this theorem by giving a nondeterministic polynomial time Turing machine for *SUBSET-SUM* as follows.

N = “On input $\langle S, t \rangle$:

1. Nondeterministically select a subset c of the numbers in S .
2. Test whether c is a collection of numbers that sum to t .
3. If the test passes, *accept*; otherwise, *reject*.”

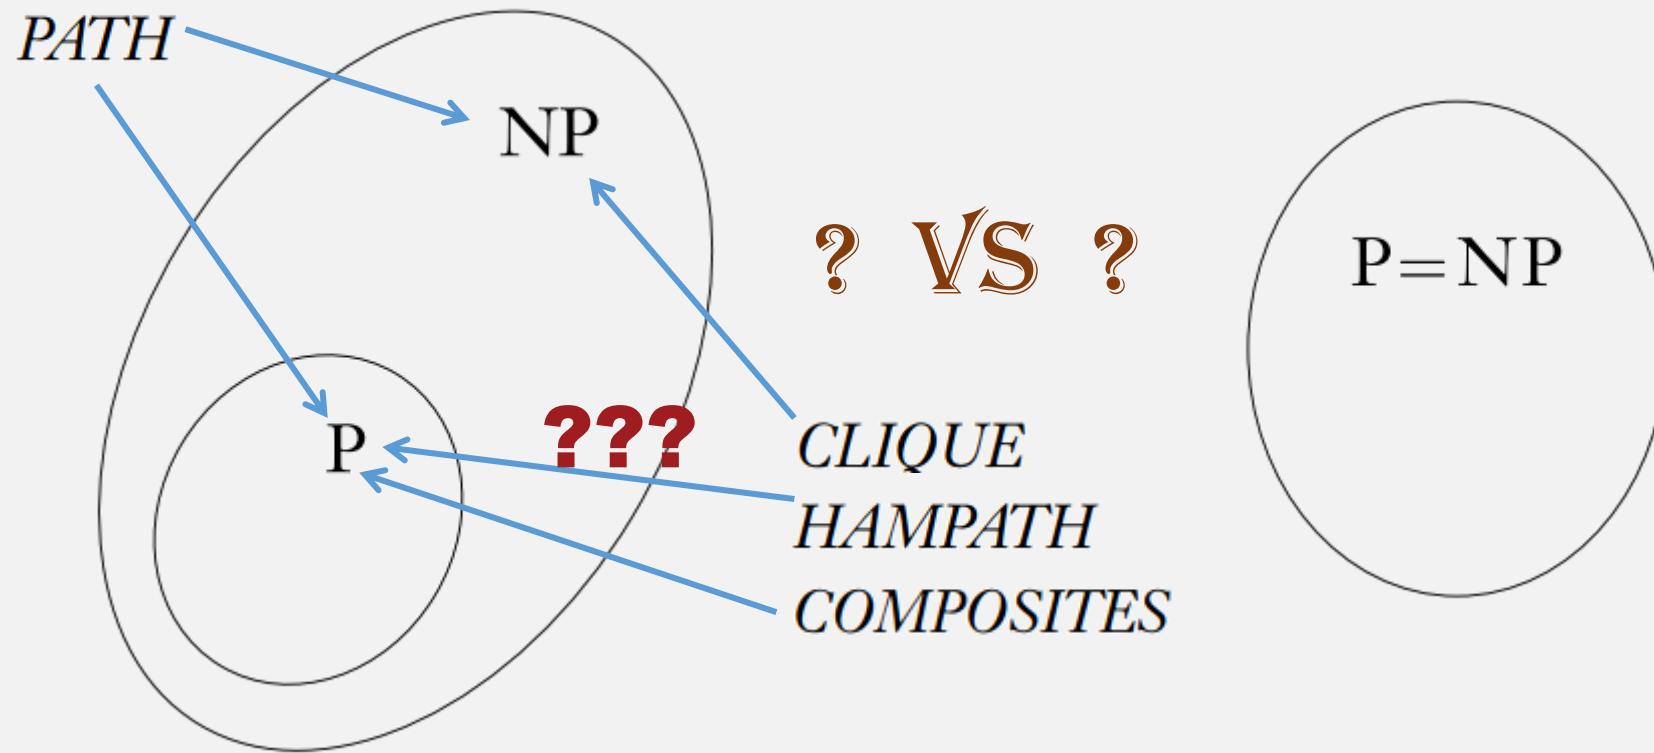

Runtime?

$$COMPOSITES = \{x \mid x = pq, \text{ for integers } p, q > 1\}$$

- A composite number is not prime
- *COMPOSITES* is polynomially verifiable
 - i.e., it's in **NP**
 - i.e., factorability is in **NP**
- A certificate could be:
 - Some factor that is not 1
- Checking existence of factors (or not, i.e., testing primality) ...
 - ... is also poly time
 - But only discovered recently (2002)!

One of the Greatest unsolved

~~HW~~ Question: Does $P = NP$?

How do you prove an algorithm doesn't have a poly time algorithm?
(in general it's hard to prove that something doesn't exist)

Implications if $P = NP$

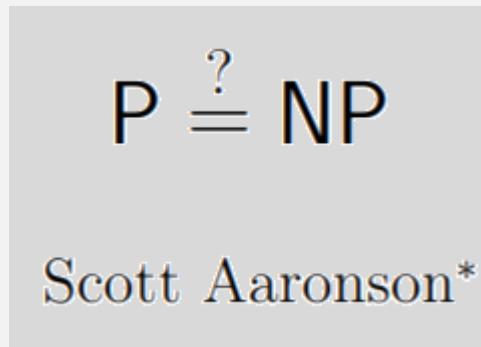

- Every problem with a “brute force” solution also has an efficient solution
- I.e., “unsolvable” problems are “solvable”
- BAD:
 - Cryptography needs unsolvable problems
 - Near perfect AI learning, recognition
- GOOD: Optimization problems are solved
 - Optimal resource allocation could fix all the world’s (food, energy, space ...) problems?

Who doesn't like niche NP jokes?

Progress on whether $P = NP$?

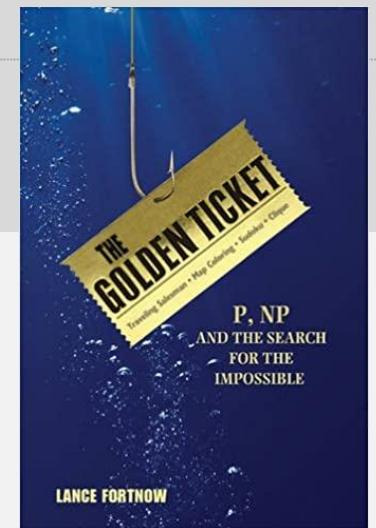

- Some, but still not close

The Status of the P Versus NP Problem

By Lance Fortnow

Communications of the ACM, September 2009, Vol. 52 No. 9, Pages 78-86
[10.1145/1562164.1562186](https://doi.org/10.1145/1562164.1562186)

- One important concept discovered:
 - NP-Completeness

NP-Completeness

Must look at all langs, can't just look at a single lang

DEFINITION

A language B is **NP-complete** if it satisfies two conditions:

1. B is in NP, and **easy**
2. **every A in NP** is polynomial time reducible to B . **hard????**

- How does this help the $P = NP$ problem?

What's this?

THEOREM

If B is NP-complete and $B \in P$, then $P = NP$.

Flashback: Mapping Reducibility

Language A is **mapping reducible** to language B , written $A \leq_m B$, if there is a computable function $f: \Sigma^* \rightarrow \Sigma^*$, where for every w ,

$$w \in A \iff f(w) \in B.$$

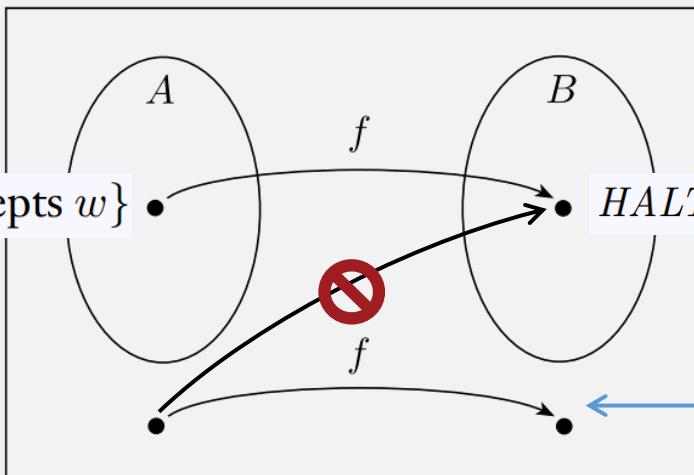

IMPORTANT: “if and only if” ...

The function f is called the **reduction** from A to B .

To show **mapping reducibility**:

1. create **computable fn**
2. and then show **forward direction**
3. and **reverse direction**
(or **contrapositive of forward direction**)

$$A_{\text{TM}} = \{\langle M, w \rangle \mid M \text{ is a TM and } M \text{ accepts } w\}$$

... means $\overline{A} \leq_m \overline{B}$

A function $f: \Sigma^* \rightarrow \Sigma^*$ is a **computable function** if some Turing machine M , on every input w , halts with just $f(w)$ on its tape.

Polynomial Time Mapping Reducibility

Language A is *mapping reducible* to language B if there is a computable function $f: \Sigma^* \rightarrow \Sigma^*$,

$$w \in A \iff f(w) \in B.$$

The function f is called the *reduction* from A to B .

To show poly time mapping reducibility:

1. create **computable fn**
2. show **forward direction**
3. show **reverse direction**
(or **contrapositive of forward direction**)
4. then **show computable fn runs in poly time**

Language A is *polynomial time mapping reducible*, or simply *polynomial time reducible*, to language B , written $A \leq_P B$, if a polynomial time computable function $f: \Sigma^* \rightarrow \Sigma^*$ exists, where for every w ,

$$w \in A \iff f(w) \in B.$$

Don't forget: "if and only if" ...

The function f is called the *polynomial time reduction* of A to B .

A function $f: \Sigma^* \rightarrow \Sigma^*$ is a **computable function** if some Turing machine M , on every input w , halts with just $f(w)$ on its tape.

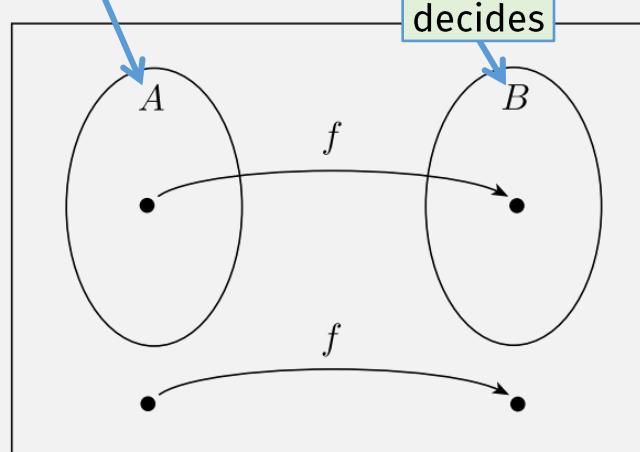

Flashback: If $A \leq_m B$ and B is decidable, then A is decidable.

Has a decider

PROOF We let M be the decider for B and f be the reduction from A to B . We describe a decider N for A as follows.

N = “On input w :

1. Compute $f(w)$.
2. Run M on input $f(w)$ and output whatever M outputs.”

This proof only works because of the if-and-only-if requirement

Language A is **mapping reducible** to language B , written $A \leq_m B$, if there is a computable function $f: \Sigma^* \rightarrow \Sigma^*$, where for every w ,

$$w \in A \iff f(w) \in B.$$

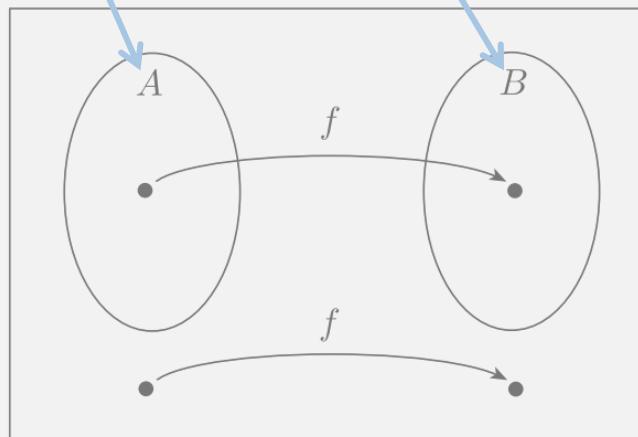

The function f is called the **reduction** from A to B .

Thm: If $A \leq_m^P B$ and B is decidable, then $A \in P$.

PROOF We let M be the decider for B and f be the reduction from A to B . We describe a decider N for A as follows.

N = “On input w :

1. Compute $f(w)$.
2. Run M on input $f(w)$ and output whatever M outputs.”

Language A is *mapping reducible* to language B , written $A \leq_m B$, if there is a computable function $f: \Sigma^* \rightarrow \Sigma^*$, where for every w ,

$$w \in A \iff f(w) \in B.$$

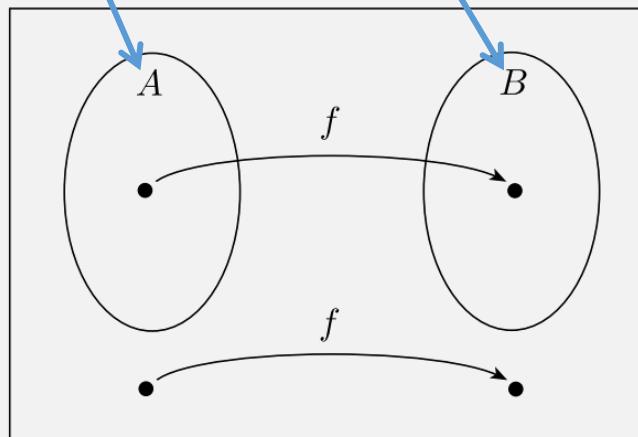

The function f is called the *reduction* from A to B .

Thm: If $A \leq_m^P B$ and B is decidable, then $A \in P$.

PROOF We let M be the decider for B and f be the reduction from A to B .
We describe a decider N for A as follows.

N = “On input w :

1. Compute $f(w)$.
2. Run M on input $f(w)$ and output whatever M outputs.”

poly time
Language A is *mapping reducible* to language B , written $A \leq_m B$, if there is a computable function $f: \Sigma^* \rightarrow \Sigma^*$, where for every w ,

$$w \in A \iff f(w) \in B.$$

The function f is called the *reduction* from A to B .

Next Time: $3SAT$ is polynomial time reducible to $CLIQUE$.
